without replacement, so the samples were independent.) Comparison 3: W1, W2 white samples from comparison 1 and comparison is defined by three parameters: (a) the *a* parameter is proportional to the slope of the curve at the inflection point and represents the item's discrimination; (b) the *b* parameter reflects the item's difficulty and is a location on the  $\theta$ ability dimension (when there is no guessing, *b* is the point where the probability of getting the item correct is 50%); and (c) the *c* parameter is often

intervals on the  $\theta$  scale and using the midpoint of each interval. Thus, probability differences in the region where the most data occur will contribute more to the index.

$$SOS1_{i} = \frac{1}{n_{W} + n_{B}} \sum_{j=1}^{n_{W} + n_{B}} \{\hat{P}_{iW}(\theta_{j}) - \hat{P}_{iB}(\theta_{j})\}^{2}.$$

The *j* subscript counts all instances of  $\theta$  for either group  $(n_W + n_B)$ . When  $\theta_j$  is a hybrid relation to the second state of  $\theta_j$  is the second state of  $\theta_j$ .

Signed area (SA). When the ICCs for two groups did not cross in the region from -3 to +3, the SA was equal to the UA except that a negative sign was attached if the item was biased against whites, if whites had a lower probability of getting the item right given  $\theta$ . If the ICCs did cross,  $\theta^*$  was found as the root of the equation  $B_{\rm es}(\theta) = P_{\rm es}(\theta)$ . Then the integral was evaluated from -3 to  $\theta^*$ 

and  $\theta^*$  to +3. The signed area was the difference between these two areas and carried the sign of the larger area. From an Brughen ? (SAS2) SAS2 is the "rised and allow a summary analogous to SOS1. By multiplying  $[\hat{P}_{iW}(\theta) - \hat{P}_{iB}(\theta)]$  times its absolute value, without than equating the difference the sign of the difference is measured

value greater than one was retained for rotation. An oblique solution was obtained by direct oblimin transformation with  $\Delta = 0$  (Harman, 1967). In the math test, the first unrotated factor accounted for 30% of the total

will be explored. Here, we wish to discuss some methodological issues regarding the functioning of the bias statistics. Results are presented for both tests to check on the generalizability of study findings.

To examine the relationships between indices, within-study correlations were obtained for each comparison on each test. Tables II and III contain the within-comparison coefficients for the math and vocabulary tests respec-

at least one or both of the comparisons were between equivalent groups (either both white or both black). These correlations should show discriminant validity or the lack of method-specific correlations. These correlations should be near zero, confirming a lack of bias when none exists conceptually. However, it should be noted that these pairs of comparisons do share some consistent errors because one sample is repeated in both comparisons. For example, we expect the correlation between indices obtained in the W1, B1 study and those from the B1, B2 study to correlate zero. Bias can be present in the first

In practical terms we wished to quantify the effect of having biased items in the test. Therefore, we rescored the math test, deleting the seven items found to be consistently biased against blacks. We compared the new black and

<u> </u>	

should be no bias. The largest values obtained in the white-white comparison were used as baselines for interpreting the size of indices in the between-ethnic comparisons. Because two items in the white-white analysis stood out as different from the typical range of values, the indices from the second-most discrepant item were used to establish the cutoffs.

The methodological results from the vocabulary test were discussed earlier

The validity and sensitivity of the IRT bias indices were supported by several findings:

1. A relatively large number of items (10 of 29) on the math test was found to be consistently biased; the results were replicated in parallel analyses. (Seven were biased against blacks, three were biased against whites.)

2. The bias indices were substantially smaller in white-white analyses. That is, with the exception of one or two estimation artifacts, indices did not find bias in situations of no bias.

## Acknowledgments

We wish to thank the Council on Research and Creative Work and Dean Richard
